Name:

Say hello to our tiny, chirping friend, the house cricket! These little creatures are usually light brown in color and have six legs with two long antennae on their heads. They grow up to be about an inch long and have wings, although they prefer to hop rather than fly. If you look really closely, you might even see the lines on their body, which look like a pattern of tiny dots!

Remember those interesting patterns we talked about? Well, our house cricket pals use those patterns, along with their brown color, to hide from predators in their natural habitats. They can be found all around the world, but tend to make their homes in warm environments, often hiding in cracks, crevices, or under stones during the day. At night, when it's safer, they come out to look for food, munching on plants, fabric and even other insects!

Speaking of food, did you know that the cycle of life for these crickets starts from an egg? A female house cricket can lay hundreds of eggs that hatch into tiny baby crickets called nymphs, and these nymphs then grow into adults in just a few weeks. Despite their small size, house crickets have a big role in the ecosystem, serving as food for a variety of animals like birds, spiders, and even other insects. They also help break down plant material, returning important nutrients back to the soil.

You might have guessed from their name that house crickets can sometimes be found in our homes, too. They are not harmful to humans, and some people even keep them as pets or use them as food for their pet reptiles. While their constant chirping can be annoying for some, in many cultures around the world, the chirping of crickets is considered to be a sign of good luck. So next time you see a house cricket, remember, they're not just tiny creatures, they're an important part of our big, wide world!

House Crickets

#### Solve each problem.
